2. Experimental section

2.1. Chemicals

All the chemicals were purchased from Sigma-Aldrich unless otherwise specified. All of the solutions were prepared using ultrapure water (18.2 MΩ). Stock solutions of metallic salts and peptides were prepared by dissolving the salts or the peptides in ultrapure water; the concentrations were determined using UV–vis absorption spectroscopy. A stock solution of Zn(II) ions was prepared at 100 mM using monohydrated ZnSO$_4$$\cdot$H$_2$O salt. A stock solution of Cu(II) was prepared at 100 mM using hydrated CuSO$_4$$\cdot$5H$_2$O salt. The concentration of the Cu(II) stock solution was determined using UV–vis ($\lambda =$ 800 nm corrected at 400 nm) while considering a molar extinction coefficient of 12 M$^{-1}$·cm$^{-1}$. A stock solution of HEPES buffer (sodium salt of 2-[4-(2-hydroxyethyl)piperazin-1-yl]ethanesulfonic acid) was prepared at 500 mM and the pH was adjusted to 7.4 using concentrated sodium hydroxide. All pH values are given with a ±0.1 pH unit error. The stock solution of sodium ascorbate were prepared at 5 mM every day due to its auto-oxidation in solution. The Aβ$_{1-16}$ (DAEFRHDSGYEVHHQK) peptide was purchased from Genecust (purity > 95%). A stock solution and its concentration was determined using UV–vis absorption spectroscopy with Tyr10 absorption considered as free tyrosine (in acidic condition, $\varepsilon_{276} = 1150$ M$^{-1}$·cm$^{-1}$). Stock solutions of ligands were prepared and concentration was determined by a Cu(II) titration followed by UV–vis absorption spectroscopy (see Figure S1 as a matter of example). The stock solutions of ligands and peptide were stored at −20 °C.
2.2. Synthesis of the ligands

All experiments were carried out in methanol or ethanol purchased from VWR chemicals without further purifications. NMR spectra were recorded on Brucker Avance 300 MHz spectrometers. $^1$H NMR spectra were referenced to residual protonated solvents ($\delta_H = 4.79$ ppm for D$_2$O). Reactions were monitored by TLC on silica gel Alugram® Xtra SIL G/UV254.

All the ligands but $^{5}L'$ were obtained according to reported protocols. Using similar procedures to those reported previously, the ligands $^{1}L$, $^{1}L'$ [2] on the one hand and ligands $^{3}L$ and $^{3}L'$ [4] on the other hand were synthesized in two steps from 2-hydroxybenzaldehyde or 4-formyl-3-hydroxybenzenesulfonic acid [5], respectively. To that end, the required aldehydes were condensed on ethylene diamine or rac(1,2)-cyclohexanediamine to yield the corresponding diimine intermediates. Diamines $^{1}L$, $^{1}L'$ and $^{5}L$ were readily obtained using NaBH$_4$ as reductive agent. However, PtO$_2$ catalytic hydrogenation was required to obtain pure ligand $^{5}L'$. Subsequent N-methylation of compounds $^{1}L$ and $^{1}L'$ was achieved by reductiveamination with an excess of formaldehyde to form the intermediate imine, followed by reduction in the presence of NaBH$_4$ to give diimines $^{1}L$$_{Me}$ [1] and $^{1}L'$$_{Me}$ [6].

Their characterization by $^1$H NMR spectroscopy correspond to the one described in the literature.

Ligand $^{5}L'$ was obtained according to an alternative protocol:

A mixture of 4-formyl-3-hydroxybenzenesulfonic acid (424 mg, 2.1 mmol) and (±)-trans-1,2-diaminocyclohexane (115 mg, 1 mmol) was refluxed in EtOH for 20 h. The reaction mixture is cooled to room temperature, and the precipitated diimine was collected by filtration (322 mg, 68% yield) and used in the next step without further purification.

The latter diimine (70 mg, 0.14 mmol) was suspended in absolute EtOH (11 mL), PtO$_2$ was added (10 mg) and the reaction mixture was subjected to catalytic hydrogenation at 5 atm for 24 h and room temperature. Filtration and concentration under vacuum yielded the expected ligand $^{5}L'$ (55 mg, 80% yield) as a white solid [4].

$^1$H NMR (300 MHz, D$_2$O): $\delta = 7.60$ (m; 4H); 6.81 (d; $J' = 9.2$ Hz; 2H); 4.11 (d; $J = 13.4$ Hz; 2H); 3.94 (d; $J = 13.4$ Hz; 2H; H$_6'$); 2.70 (m; 2H); 2.24 (m; 2H); 1.77 (m; 2H); 1.28 (m; 4H).

HR-MS: (DCI-CH$_4$) calculated for C$_{20}$H$_{27}$N$_2$O$_8$S$_2$ [MH]$^+$ = 487.1209; found: 487.1206 m/z.

2.2.1. UV–visible spectroscopy

Titration and UV–vis kinetic data from the ascorbate consumption experiments were recorded with a Hewlett Packard Agilent 8453 or 8454 spectrophotometer at a controlled temperature of 25 °C in a 1 cm path length quartz cuvette with 800 rpm stirring.

2.2.2. Cu$^{II}$ titration

The concentrations of ligands stock solutions were determined via Cu$^{II}$ titration with a solution of known concentration using the d–d and LMCT transition absorption of the formed complex (see for example Figure S1 for the titration of ligand L). All the ligands were titrated at about 500 µM (based on weighting) with the addition of an increasing amount of a Cu$^{II}$ stock solution. For competition experiment, Cu$^{II}$ and Aβ were added to the cuvette to preform Cu$^{II}$(Aβ) complex and $\mathcal{L}$ was added after.

Supplementary Figure S1. UV–vis spectra corresponding to the titration of Cu$^{II}$ into a solution of ligand L. Inset: Absorbance at 600 nm versus number of Cu$^{II}$ equiv. added. [hepes] 50 mM, pH 7.4, $T = 25$ °C, [L] is approx. 500 µM; 1 equiv. of Cu$^{II}$ = 500 µM.
**Supplementary Figure S2.** Cu\textsuperscript{II} removal from Cu\textsuperscript{II}(A\beta) by \textit{LLL} followed by UV–vis. Each panel contains spectra of Cu\textsuperscript{II}(A\beta) (black curves), Cu\textsuperscript{II} (L) (L in pink, L\textsubscript{Me} in blue, L\textquotesingle in green, S\textsubscript{L} in light pink, S\textsubscript{L}\textquotesingle in light green and S\textsubscript{L}\textsubscript{Me} in light green), and spectra of the addition of L to Cu\textsuperscript{II}(A\beta) with mixing for 5 min (thick curves). Experimental conditions: [Cu\textsuperscript{II}] = 500 µM, [L] = [A\beta] = 500 µM, [HEPES] = 100 mM, pH 7.4, T = 25 °C.
Supplementary Figure S3. Cu\textsuperscript{II} removal from Cu\textsuperscript{II} (Aβ) and Cu\textsuperscript{II} Zn\textsuperscript{II} (Aβ) by L\text{L} followed by X-band EPR. Each panel contains spectra of Cu\textsuperscript{II} (Aβ) (black curves), Cu\textsuperscript{II} (L\text{L}) and of the addition of L\text{L} to Cu\textsuperscript{II} (Aβ) (thick curve) and Cu\textsuperscript{II} Zn\textsuperscript{II} (Aβ) (doted curve) and mixing for 5 min. Experimental conditions: [\textsuperscript{65}Cu\textsuperscript{II}] = 480 µM, [L\text{L}, Aβ] = 500 µM, or [\textsuperscript{65}Cu\textsuperscript{II}] = [Zn] = 180 µM, [L\text{L}, Aβ] = 200 µM [HEPES] = 50 mM, pH 7.4, 10% of glycerol as cryoprotectant, \(T = 120\) K, \(\nu \approx 9.5\) GHz, mod. ampl. = 5 G, microwave power: 5 mW.
Supplementary Figure S4. Cu\textsuperscript{II} removal from Cu\textsuperscript{II}(A\textbeta) and Cu\textsuperscript{II} by $L'_\text{Me}$ monitored by UV–vis. Experimental conditions: $[L'_\text{Me}] = [\text{Cu(II)}] = [\text{Zn(II)}] = [A\beta] = 500$ µM, [HEPES] = 100 mM, pH 7.4, $T = 25$ °C. Cu(II)A\beta was pre-formed in the cuvette and then, $L'_\text{Me}$ was added at 500 s in red: absorbance at 392 nm and in black at 620 nm.

2.2.3. ROS experiment

The ROS production was determined using an ascorbate consumption assay monitored via UV–vis spectroscopy. The decrease in the absorption band at $\lambda_{\text{max}} = 265$ nm of the Asc ($\varepsilon = 14,500$ M$^{-1}$·cm$^{-1}$, corrected at 800 nm for the background absorption) was plotted as a function of time.

The samples were prepared from stock solutions at 1 mM and mixed in situ in the UV–vis cuvette at a final concentration of 12 µM for $\mathcal{L}$, A\beta\textsubscript{1-16}, and Zn\textsuperscript{II} and 10 µM for Cu\textsuperscript{II} in HEPES at pH 7.4. Ascorbate was added to obtain 100 µM as the final concentration. The final volume was adjusted with ultrapure water to 2 mL. The ROS experiments were performed following three different procedures: (i) starting from Cu(II) with 300 s incubation time where Cu\textsuperscript{II}/Zn\textsuperscript{II}, A\beta and $\mathcal{L}$ were added at 30, 60 and 120 s respectively; (ii) with long enough incubation time to reach the thermodynamic equilibrium where Cu\textsuperscript{II} + A\beta + $\mathcal{L}$ or Cu\textsuperscript{II} + A\beta + Zn\textsuperscript{II} + $\mathcal{L}$ mixtures were prepared out of the cuvette, in Eppendorf tubes, and incubated at 25 °C with stirring. These experiments are

Supplementary Figure S5. Continued on next page.
Supplementary Figure S5. (cont.) Ascorbate consumption induced by Cu(Aβ). Starting from Cu(II) (in presence of increasing Zn stoichiometry, A, B and C) and with Ascorbate added 300 s after mixing of the others chemicals, $[\mathbf{L}] = [\text{Aβ}] = [\text{Zn}^{II}] = 0, 12$ and $120 \, \mu\text{M}$, $[\text{Cu}^{II}] = 10 \, \mu\text{M}$, $[\text{Asc}] = 100 \, \mu\text{M}$, $[\text{HEPES}] = 100 \, \text{mM}$, pH 7.4, $T = 25 \, ^\circ\text{C}$. The arrows indicate the time at which the different components are added into the cuvette.

called “A” in the main text. Third, (iii) with the ligand added in the course of Asc consumption (experiment called “B”) where ascorbate was first introduced into the cuvette, then, either $\text{Cu}^{II} + \text{Aβ} + \mathbf{L}$ or $\text{Cu}^{II} + \text{Aβ} + \text{Zn}^{II} + \mathbf{L}$ was added. Ascorbate, Aβ, and/or Zn II and Cu II were added at 30, 120, and 240 s, respectively. When the absorbance reached about 1.1 in O.D., $\mathbf{L}$ was added. These experiments were run under aerobic conditions.

2.2.4. EPR

Electron paramagnetic resonance (EPR) spectra were recorded using an Elexsys E-500 Bruker spectrometer operating at a microwave frequency of approximately 9.5 GHz. The spectra were recorded using a microwave power of 5 mW, a magnetic field range of 2400 to 3700 G, and a modulation amplitude of 5 G. The experiments were carried out at 120 K using a liquid nitrogen cryostat. EPR samples were prepared in Eppendorf tubes from a 10 mM $^{65}\text{Cu}^{II}$ and Aβ stock solution and diluted to 480 µM and 500 µM respectively in 50 mM of HEPES buffer (pH 7.4) with the addition of 500 µM of ligands. Experiment with Zn II were conducted at 200 µM to limit precipitation. As a cryoprotectant, 10% glycerol was added. The final volume was adjusted to 200 µL using ultrapure water. The mixture was then transferred into a EPR quartz tube and frozen in liquid nitrogen.

Supplementary Figure S6. Ascorbate consumption induced by Cu(Aβ) and effect of pre-incubation of $L'_{Me}$ (times are given in the figure). $[L'_{Me}] = [A\beta] = 12 \, \mu\text{M}, [\text{Cu}^{II}] = 10 \, \mu\text{M}, [\text{Asc}] = 100 \, \mu\text{M}, [\text{HEPES}] = 100 \, \text{mM}$, pH 7.4, $T = 25 \, ^\circ\text{C}$. Ascorbate was added at 30 s (after having taken the starting spectrum corresponding to the incubated mixture).
Supplementary Figure S7. Ascorbate consumption induced by Cu,Zn(Aβ) with Zn^{II} 10 eq and effect of pre-incubation of L (left: 1 h of CuZn(Aβ) + L incubation and right: 24 h of CuZn(Aβ) + L incubation). [L] = [Aβ] = 12 µM, [Zn^{II}] = 120 µM, [Cu^{II}] = 10 µM, [Asc] = 100 µM, [HEPES] = 100 mM, pH 7.4, T = 25 °C. Ascorbate was added at 30 s (after having taken the starting spectrum corresponding to the incubated mixture). Solutions of ligands L and Cu, Zn(Aβ) were pre-incubated at room temperature, with agitation and at experimental concentrations.

Supplementary Scheme S2. Scheme of the ligands from Ref. [7]. Charges are omitted for simplicity.
