## Abstract

We give a construction of a reflexive Banach space  $X_{\omega_1}$  with a transfinite basis of length  $\omega_1$  and with no unconditional basic sequence. In addition every bounded operator from a subspace of  $X_{\omega_1}$  into the space  $X_{\omega_1}$  is a sum of a simple diagonal operator and a strictly singular one. *To cite this article: S.A. Argyros et al., C. R. Acad. Sci. Paris, Ser. I 337 (2003).*

## Résumé

**Une classe d'espace de Banach sans suite basique inconditionnelle.** Nous construisons un espace de Banach réflexif  $X_{\omega_1}$  ayant une base transfinie de longueur  $\omega_1$  et n'admettant aucune suite basique inconditionnelle. De plus, tout opérateur borné d'un sous-espace de  $X_{\omega_1}$  dans cet espace est somme d'un opérateur diagonal très simple et d'un opérateur strictement singulier. *Pour citer cet article : S.A. Argyros et al., C. R. Acad. Sci. Paris, Ser. I 337 (2003).*

## Version française abrégée

Il est bien connu depuis plus de trente ans que tout espace de Banach  $X$  réflexif non séparable peut être décomposé en morceaux séparables par une longue suite de projections (voir [8]). Par conséquent,  $X$  admet des projections de norme 1 sur des sous-espaces séparables de dimension infinie. Cependant, il n'est pas du tout clair que l'algèbre de Banach engendrée par la suite de projections épuise, à petite perturbation près, l'algèbre de tous les opérateurs bornés sur  $X$ . Nous construisons un espace réflexif non séparable  $X_{\omega_1}$  ayant cette propriété et qui est, en plus, purement non inconditionnel. Une propriété remarquable de  $X_{\omega_1}$  est qu'il n'est isomorphe à aucun de ses hyperplans. De plus, dans l'esprit des travaux de Gowers [6], nous construisons une version inconditionnelle de  $X_{\omega_1}$ , qui est un espace réflexif non séparable ayant une base inconditionnelle sur lequel aucun shift n'est borné, tout opérateur borné s'écrivant comme  $D + S$ , où  $D$  est diagonal et  $S$  est strictement singulier d'image séparable.

Plus précisément, nous construisons une famille  $X_\gamma$  ( $\gamma \leq \omega_1$ ) d'espaces de Banach réflexifs ayant une longue base transfinie, mais sans suite basique inconditionnelle. Pour décrire une telle suite d'espaces conditionnellement saturés et ayant beaucoup de projections il est nécessaire d'introduire des fonctionnelles dit « spéciales » qui imposeront cette conditionnalité. Cette construction, comme dans le cas de travail de Gowers et Maurey [7], dépend de façon cruciale d'un certain codage  $\sigma_\rho$  de suites finies de fonctionnelles. La différence essentielle avec le codage utilisé dans [7] est que  $\sigma_\rho$  n'est pas une injection, la propriété dont dépend les démonstrations de Gowers et Maurey. Nos démonstrations reposent sur une propriété « tree-like » du codage. Comme conséquence, sur chaque  $X_\gamma$  tout opérateur borné a une forme très simple.

**Théorème 0.1.** *Soit  $T : X_\gamma \rightarrow X_\gamma$  un opérateur borné. Alors il existe un opérateur diagonal borné  $D_T : X_\gamma \rightarrow X_\gamma$  tel que  $T - D_T$  soit strictement singulier et tel que  $D_T e_\alpha = D_T e_{\alpha+n}$ ,  $\alpha < \gamma$  successeur.*

Comme les espaces  $X_\gamma$  ont des bases longues transfinies, l'algèbre  $\mathcal{D}(X_\gamma)$  d'opérateurs de forme  $D_T$  est très riche. Dans beaucoup de cas nous identifions cette algèbre

**Théorème 0.2.**  *$\mathcal{D}(X_{\omega_2})$  est isomorphe au dual de l'espace quasi-réflexif de James  $J_{T_0}$ , basé sur l'espace « mixed » de Tsirelson  $T_0$  (cf. [1]).*

La propriété suivante est également remarquable.

**Théorème 0.3.** *Tout sous-espace de dimension finie de chaque  $X_\gamma$  peut être recopié par un  $(4 + \varepsilon)$ -isomorphisme dans n'importe quelle région de tout autre  $X_\delta$ .*

Nous donnons aussi pour chaque  $\gamma$  un sous-espace  $X \hookrightarrow X_\gamma$  tel que l'espace  $\mathcal{L}(X, X_\gamma)$  soit très riche, mais tout opérateur borné  $T$  de  $X$  dans  $X$  soit une variation strictement singulière d'un multiple de l'identité.

## 1. Introduction

We construct a family  $X_\gamma$  ( $\gamma \leq \omega_1$ ) of reflexive Banach spaces with long transfinite bases but with no unconditional basic sequences. To describe such a family of conditionally saturated Banach spaces with many projections it was necessary to introduce a new construction of the so-called special functionals that impose this conditionality. In our spaces  $X_\gamma$  every bounded operator  $T$  is split into its diagonal part  $D_T$  and its strictly singular part  $S_T$ . Having long transfinite bases our spaces  $X_\gamma$  have rich spaces  $\mathcal{D}(X_\gamma)$  of diagonal operators. Rather unexpectedly, in many cases we were able to identify the spaces  $\mathcal{D}(X_\gamma)$ . For example, we show that  $\mathcal{D}(X_{\omega_2})$  is isomorphic to the dual of the quasi-reflexive Banach space  $J_{T_0}$ , the James space over the mixed Tsirelson space  $T_0$  (see [1]). We discover several other new phenomena by looking at subspaces  $X$  of our spaces  $X_\gamma$ . For example, we show that every finite-dimensional subspace of any  $X_\gamma$  can be moved by an  $(4 + \varepsilon)$ -isomorphism to essentially any region of any other member  $X_\delta$  of our class. We also find subspaces  $X$  of  $X_\gamma$  such that the operator space  $\mathcal{L}(X, X_\gamma)$  is quite rich but any bounded operator  $T$  from  $X$  into  $X$  is a strictly singular variation of a scalar multiple of the identity.

## 2. The norming set

The maximal space in our class  $X_{\omega_1}$  will be defined as the completion of  $(c_{00}(\omega_1), \|\cdot\|_{\omega_1})$  under the norm  $\|\cdot\|_{\omega_1}$  induced by a set of functionals  $K_{\omega_1} \subseteq c_{00}(\omega_1)$ .

### 2.1. Definition of $K_{\omega_1}$

Let  $(m_j)_j, (n_j)_j$  be the two sequences defined recursively as follows:  $m_1 = 2$ ,  $n_1 = 4$ ,  $m_{j+1} = m_j^5$ , and  $n_{j+1} = (5n_j)^{s_j}$  for  $s_j = \log_2(m_{j+1})$ . The set  $K_{\omega_1}$  is the minimal subset of  $c_{00}(\omega_1)$  satisfying that: (1) It contains  $(e_\gamma^*)_{\gamma < \omega_1}$ , is symmetric and is closed under the restriction on intervals of  $\omega_1$ . (2)  $\phi = \frac{1}{m_{2j}} \sum_{i=1}^{n_{2j}} \phi_i \in K_{\omega_1}$  for  $\{\phi_i : i = 1, \dots, n_{2j}\} \subseteq K_{\omega_1}$  with  $\text{supp } \phi_1 < \dots < \text{supp } \phi_{n_{2j}}$ , and we say that  $\phi$  is a result of a  $(1/m_{2j}, \mathcal{A}_{n_{2j}})$

operation. (3)  $\phi = \frac{1}{m_{2j+1}} \sum_{i=1}^{n_{2j+1}} \phi_i \in K_{\omega_1}$  for special sequences  $(\phi_1, \dots, \phi_{n_{2j+1}}) \subseteq K_{\omega_1}$  (see Subsection 2.3) and we say that  $\phi$  is a result of a  $(1/m_{2j+1}, \mathcal{A}_{n_{2j+1}})$  operation. (4) It is rationally convex. The norm on  $c_{00}(\omega_1)$  is defined as  $\|x\|_{\omega_1} = \sup\{\phi(x) = \sum \phi(\alpha) \cdot x(\alpha) : \phi \in K_{\omega_1}\}$  and  $X_{\omega_1}$  is the completion of  $(c_{00}(\omega_1), \|\cdot\|_{\omega_1})$ . Each of the above four properties provides certain features in the space  $X_{\omega_1}$ . The first makes the family  $(e_\gamma)_{\gamma < \omega_1}$  a transfinite bimonotone basis of  $X_{\omega_1}$ . The second saturates  $X_{\omega_1}$  with local unconditional structure. This property will be responsible for the existence of seminormalized averages in every block sequence of  $X_{\omega_1}$ . The third property saturates  $X_{\omega_1}$  with conditional structure and will make impossible for  $X_{\omega_1}$  to contain any unconditional basic sequence. Finally, the fourth property is a tool for proving properties of the space of operators from an arbitrary subspace  $X$  of  $X_{\omega_1}$  into  $X_{\omega_1}$ . The above definition, with the exception of the missing definition of special sequences, is based on the corresponding definitions from [2] and [3] which in turn are variants of the construction from [7]. By the minimality of  $K_{\omega_1}$  each  $\phi \in K_{\omega_1}$  has one of the following forms: (i)  $\phi$  is of type 0 if  $\phi = \pm e_\alpha^*$ . (ii)  $\phi$  is of type I if  $\phi = \pm E f$  for  $f$  a result of one  $(1/m_j, \mathcal{A}_{n_j})$  operation and  $E$  an interval. (iii)  $\phi$  is of type II if  $\phi$  is a rational convex combination of type 0 and type I functionals.

**Definition 2.1.** For  $\phi \in K_{\omega_1}$  of type I we define the *weight* of  $\phi$ , denoted by  $w(\phi)$ , to be  $m_j$  if  $\phi$  is the result of an  $(\frac{1}{m_j}, \mathcal{A}_{n_j})$  operation. Notice that  $\phi \in K_{\omega_1}$  may have many weights.

The definition of the special sequences will, as in the case [7], depend crucially on certain coding  $\sigma_\rho$ . The essential difference is that now  $\sigma_\rho$  is not an injection, a crucial property on which the proofs in [7] rely. Our proofs on the other hand will rely on a ‘tree-like property’ of our coding which we now describe. First we notice that each  $2j + 1$ -special sequence  $\Phi = (\phi_1, \phi_2, \dots, \phi_{n_{2j+1}})$  is of the form  $\text{supp } \phi_1 < \dots < \text{supp } \phi_{n_{2j+1}}$  with each  $\phi_i$  of type I. The *tree-like property* is the following: For any pair of  $2j + 1$ -special sequences  $\Phi = (\phi_1, \phi_2, \dots, \phi_{n_{2j+1}})$ ,  $\Psi = (\psi_1, \psi_2, \dots, \psi_{n_{2j+1}})$  there exist  $1 \leq k_{\Phi, \Psi} \leq \lambda_{\Phi, \Psi} \leq n_{2j+1}$  such that (i) If  $1 \leq k < k_{\Phi, \Psi}$  then  $\phi_k = \psi_k$  and if  $k_{\Phi, \Psi} < k < \lambda_{\Phi, \Psi}$  then  $w(\phi_k) = w(\psi_k)$ . (ii)  $(\bigcup_{k_{\Phi, \Psi} < k < \lambda_{\Phi, \Psi}} \text{supp } \phi_k) \cap (\bigcup_{k_{\Phi, \Psi} < k < \lambda_{\Phi, \Psi}} \text{supp } \psi_k) = \emptyset$ . (iii)  $\{w(\phi_k) : \lambda_{\Phi, \Psi} < k < n_{2j+1}\} \cap \{w(\psi_k) : \lambda_{\Phi, \Psi} < k < n_{2j+1}\} = \emptyset$ .

Comparing the above tree-like property with the corresponding property from [7], we notice that the new ingredient is the number  $\lambda_{\Phi, \Psi}$ . Its occurrence is a byproduct of the fact that the coding  $\sigma_\rho$  is not one-to-one. The property (ii) will however give us a sufficient control of our special functionals.

### 2.2. $\rho$ -functions

By a  $\rho$ -function we understand a function  $\rho : [\omega_1]^2 \rightarrow \omega$  such that for all  $\alpha < \beta < \gamma$  and  $n \in \omega$ : (a)  $\rho(\alpha, \gamma) \leq \max\{\rho(\alpha, \beta), \rho(\beta, \gamma)\}$  and  $\rho(\alpha, \beta) \leq \max\{\rho(\alpha, \gamma), \rho(\beta, \gamma)\}$ . (b) The set  $\{\alpha < \beta : \rho(\alpha, \beta) \leq n\}$  is finite.

The  $\rho$ -functions have been introduced in [10] (see also [11]). The following will related  $\rho$ -functions to our coding.

**Definition 2.2.** Let  $F$  be a finite subset of  $\omega_1$ . We set  $n_F = \max\{\rho(\alpha, \beta) : \alpha, \beta \in F\}$ . For  $n \in \omega$  with  $n_F \leq n$  and  $\gamma = \max F$  we define the *n-completion* of  $F$  to be the set  $\text{Cl}(F, n) = \{\alpha : \alpha \leq \gamma \text{ and } \rho(\alpha, \gamma) \leq n\}$  (convention:  $\rho(\gamma, \gamma) = 0$  for all  $\gamma$ ). The condition (b) of the definition of  $\rho$ -function yields that  $\text{Cl}(F, n)$  is finite. A finite subset  $G$  of  $\omega_1$  is said to be *n-complete* if  $\text{Cl}(G, n) = G$ .

Basic properties from the definition are that if  $F, G$  are two finite  $n$ -complete subsets of  $\omega_1$ , then for each  $\gamma \in F$  the set  $F_\gamma = \{\beta : \beta \in F, \beta \leq \gamma\}$  is also  $n$ -complete, and that if  $F \cap G \neq \emptyset$  then  $F \cap G$  defines an initial part of both  $F$  and  $G$ .

### 2.3. The $\sigma_\rho$ -coding and the special sequences

We denote by  $\mathbb{Q}_s(\omega_1)$  the following set:  $\mathbb{Q}_s(\omega_1) = \{(\phi_1, M_1, \phi_2, M_2, \dots, \phi_d, M_d, N) : 0 < d \in \omega, \phi_k \in c_{00}(\omega_1, \mathbb{Q}), \text{supp } \phi_1 < \text{supp } \phi_2 < \dots < \text{supp } \phi_d, M_1, M_2, \dots, M_d < N \in \omega, N \geq n_{\bigcup_{k=1}^d \text{supp } \phi_k}\}$  and by  $\mathbb{Q}_s$  the corresponding set when each  $\phi_k \in c_{00}(\omega, \mathbb{Q})$ .

To define  $\sigma_\rho$  we start with a one-to-one function  $\sigma : \mathbb{Q}_s \rightarrow \{2j : j \in \mathbb{N}\}$  such that  $\sigma(\phi_1, M_1, \phi_2, M_2, \dots, \phi_d, M_d, N) > \max\{N^2, \frac{1}{\varepsilon^2}, \max \text{supp } \phi_d\}$ , where  $\varepsilon = \min\{|\phi_k(e_\alpha)| : \alpha \in \text{supp } \phi_k, k = 1, \dots, d\}$ . Given a finite subset  $F$  of  $\omega_1$ , let  $\pi_F : \{1, 2, \dots, \#F\} \rightarrow F$  be the order preserving map. For  $\Phi = (\phi_1, M_1, \phi_2, M_2, \dots, \phi_d, M_d, N) \in \mathbb{Q}_s(\omega_1)$  we denote by  $G_\Phi = \text{Cl}(\bigcup_{i=1}^d \text{supp } \phi_i, N)$  and then we consider the family  $\tilde{\Phi} = (\tilde{\phi}_1, M_1, \tilde{\phi}_2, M_2, \dots, \tilde{\phi}_d, M_d, N) \in \mathbb{Q}_s$ , where  $\tilde{\phi}_k = \phi_k \circ \pi_{G_\Phi}$ . Finally, we set  $\sigma_\rho(\Phi) = \sigma(\tilde{\Phi})$ .

A sequence  $(\phi_i)_{i=1}^{n_{2j+1}}$  of functionals of  $K_{\omega_1}$  is said to be  $2j+1$  special sequence if: (i)  $\text{supp } \phi_1 < \text{supp } \phi_2 < \dots < \text{supp } \phi_{n_{2j+1}}$ , each  $\phi_k$  is of type I,  $w(\phi_k) = m_{2jk}$  and  $w(\phi_1) \geq m_{2j+1}$ . (ii) For each  $1 \leq k < n_{2j+1}$  there exists  $N_k \in \omega$  such that  $w(\phi_{k+1}) = m_{\sigma_\rho(\phi_k)}$  for  $\Phi_k = (\phi_1, w(\phi_1), \phi_2, w(\phi_2), \dots, \phi_k, w(\phi_k), N_k)$ .

### 3. The structure of $X_{\omega_1}$ and its subspaces

As we have mentioned before, the main property of  $X_{\omega_1}$  is that it does not contain any unconditional basic sequence. A more detailed description of the properties of  $X_{\omega_1}$  and its subspaces follows.

**Proposition 3.1.** (i) *The space  $X_{\omega_1}$  is reflexive.*

(ii) *The closed linear span of a block sequence of  $X_{\omega_1}$  is hereditarily indecomposable, and hence every two nonseparable subspaces of  $X_{\omega_1}$  satisfy the zero angle property.*

(iii) *For  $I_1, I_2$  infinite disjoint intervals the spaces  $X_{I_1}$  and  $X_{I_2}$  are totally incomparable.*

(iv) *Any projection  $P_Y : X_{\omega_1} \rightarrow Y$  has the form  $P = \sum_{i=1}^n P_{X_{I_i}} + S$  for  $S$  strictly singular,  $\{I_i\}_i$  intervals, and  $X_{\omega_1}$  is not isomorphic to any of its proper subspaces.*

Two additional properties of the  $\rho$ -function yield more properties of  $(X_\gamma)_{\gamma \leq \omega_1}$ .

**Definition 3.2.** A  $\rho$ -function is said to be *smooth* if for each limit ordinal  $\gamma < \omega_1$  there exists  $C_\gamma > 0$  such that  $\#\{\beta : \rho(\beta, \gamma) \leq n\} \leq C_\gamma \cdot n$  for all  $n \in \omega$ . Roughly speaking, a  $\rho$ -function is called *universal* if it has the property that its restriction on any infinite interval of  $\omega_1$  contains all the possible elementary models of  $\rho$ -functions. Functions with both properties exist.

**Proposition 3.3.** *If the coding  $\sigma_\rho$  is based on a smooth  $\rho$ -function then for each  $\gamma < \omega_1$  the transfinite basis  $(e_\beta)_{\beta < \gamma}$  can be reordered as  $(e_{\beta_n})_n$  to become a Schauder basis for  $X_\gamma$ .*

**Definition 3.4.** A transfinite basis  $(e_\gamma)_{\gamma < \delta}$  is said to be *nearly subsymmetric* if there exists  $C > 0$  such that for every family of finite successive subsets  $\{F_i\}_{i=1}^d$  of  $\delta$  and every family  $\{I_i\}_{i=1}^d$  of successive infinite intervals there exists  $\{G_i\}_{i=1}^d$  with  $G_i \subseteq I_i$ ,  $\#G_i = \#F_i$  and the order preserving map  $T : \langle (e_\alpha)_{\alpha \in \bigcup_{i=1}^d F_i} \rangle \rightarrow \langle (e_\beta)_{\beta \in \bigcup_{i=1}^d G_i} \rangle$  satisfies  $\|T\| \cdot \|T^{-1}\| \leq C$ .

**Proposition 3.5.** *If the coding  $\sigma_\rho$  is based on a universal  $\rho$ -function then the basis  $(e_\gamma)_{\gamma < \omega_1}$  is nearly subsymmetric.*

**Corollary 3.6.** *There is an H.I.-space with a nearly subsymmetric Schauder basis.*

Let us say that two basic sequences are *finitely equivalent* if there exists  $C > 0$  such that any finite subset of each one of them is  $C$ -equivalent to a finite subset of the other through the natural order preserving operator. Then the family  $\{X_{(\omega_\gamma, \omega_{\gamma+\omega})}\}_{\gamma < \omega_1}$  is an example of an uncountable family of reflexive HI spaces that are pairwise totally incomparable though their bases are pairwise finitely equivalent.

#### 4. The operator spaces

We proceed with some results regarding the structure of the space  $\mathcal{L}(X_{\omega_1})$  including the structure of  $\mathcal{L}(Y)$  with  $Y$  a subspace of  $X_{\omega_1}$ . We say that  $\xi : \omega_1 \rightarrow \mathbb{R}$  is a *step function* provided that  $\alpha \leq \beta < \alpha + \omega$  implies  $\xi(\beta) = \xi(\alpha + \omega)$ . For a given step function  $\xi : \omega_1 \rightarrow \mathbb{R}$ , the corresponding diagonal operator  $X_{\omega_1}$  is defined by  $D_\xi(e_\alpha) = \xi(\alpha)e_\alpha$ . We denote by  $\mathcal{D}(X_{\omega_1})$  the closed commutative subalgebra of  $\mathcal{L}(X_{\omega_1})$  consisting of all such diagonal operators. Similarly for  $\gamma \leq \omega_1$  we denote by  $\mathcal{D}(X_\gamma)$  the corresponding subspace of  $\mathcal{L}(X_\gamma)$ . Finally we extend this notation to the subspaces  $Y$  of  $X_{\omega_1}$  generated by a normalized block sequence  $(x_\beta)_{\beta < \gamma}$ . For any space  $Y$  we denote by  $\mathcal{S}(Y)$  the ideal of strictly singular operators, and  $\mathcal{L}(Y, X_{\omega_1}), \mathcal{S}(Y, X_{\omega_1})$  have the analogous meaning.

**Theorem 4.1.** *For every bounded operator  $T : X_{\omega_1} \rightarrow X_{\omega_1}$  there is a continuous step function  $\xi_T : \omega_1 \rightarrow \mathbb{R}$  and a strictly singular operator  $S_T : X_{\omega_1} \rightarrow X_{\omega_1}$  such that  $T = D_{\xi_T} \oplus S_T$ . Moreover (a) There exists  $C > 0$  such that  $\|D_{\xi_T}\| \leq C\|T\|$ . Hence  $\mathcal{L}(X_{\omega_1}) \cong \mathcal{D}(X_{\omega_1}) \oplus \mathcal{S}(X_{\omega_1})$ . (b) For every  $S \in \mathcal{S}(X_{\omega_1})$  the transfinite sequence  $(\|Se_\alpha\|)_{\alpha < \omega_1}$  belongs to  $c_0(\omega_1)$ .*

The corresponding results for the structure of  $\mathcal{L}(X_\gamma)$ ,  $\gamma < \omega_1$ , are similarly obtained. Namely  $\mathcal{L}(X_\gamma) \cong \mathcal{D}(X_\gamma) \oplus \mathcal{S}(X_\gamma)$ . For understanding the norm of the diagonal operators we use the well-known mixed Tsirelson space  $T_0 = \overline{\langle c_{00}, \|\cdot\|_{T_0} \rangle}$ , where  $\|x\|_{T_0} = \max\{\|x\|_0, \sup_j \sup \frac{1}{m_{2j}} \sum_{k=1}^{n_{2j}} \|E_k x\|_{T_0}\}$  and where the supremum is taken over all families  $\{E_k\}_{k=1}^n$  of successive subsets of  $\omega$ . As in the case of Schlumprecht space [9]  $T_0$  is reflexive with a subsymmetric basis. Next, for any infinite set of ordinals  $A$  we define the space  $J_{T_0}(A)$  to be the completion of  $(c_{00}(A), \|\cdot\|_{J_{T_0}})$ , where  $\|x\|_{J_{T_0}} = \sup\{\|\sum_{k=1}^n (\sum_{\alpha \in I_k} x(\alpha))e_k\|_{T_0} : \{I_k\}_{k=1}^n \text{ a family of disjoint successive intervals of } A\}$ .

The definition of  $J_{T_0}(A)$  is the natural fusion of the notion of ‘Jamesfication’ of a given Banach space introduced in [4] and the definition of the long James spaces as defined by G. Edgar [5]. In particular, for  $A = \omega$  the space  $J_{T_0} = J_{T_0}(\omega)$  is quasi-reflexive. The following is our main result regarding  $\mathcal{D}(X_\gamma)$ .

**Theorem 4.2.** *For each infinite  $\gamma \leq \omega_1$  there is some  $A \subseteq \gamma$  such that  $\mathcal{D}(X_\gamma) \cong J_{T_0}^*(A)$ .*

It follows that for a countable ordinal  $\gamma$ , the space  $\mathcal{D}(X_\gamma)$  is separable (since  $\dim J_{T_0}^*(A) = \#A$ ) and it does not contain  $c_0$ , and as a particular case  $\mathcal{D}(X_{\omega^2}) \cong J_{T_0}^*$ . The previous result is extended for operators acting on subspaces of  $X_{\omega_1}$ .

**Theorem 4.3.** *Let  $X \hookrightarrow X_{\omega_1}$ . Then for some  $\gamma \leq \omega_1$   $\mathcal{L}(X, X_{\omega_1}) \cong \mathcal{D}(X_\gamma, X_{\omega_1}) \oplus \mathcal{S}(X, X_{\omega_1})$ . If in addition  $X$  is generated by a block sequence, then  $\mathcal{L}(X) \cong \mathcal{D}(X) \oplus \mathcal{S}(X)$  and  $\mathcal{D}(X) \cong J_{T_0}^*(A)$ .*

*However, for every  $\gamma < \omega_1$  there exists a subspace  $Y_\gamma \hookrightarrow X_{\omega_1}$  such that  $\mathcal{L}(Y_\gamma) \cong \langle Id_{Y_\gamma} \rangle \oplus \mathcal{S}(Y_\gamma)$  while  $\mathcal{L}(Y_\gamma, X_{\omega_1}) \cong \mathcal{D}(X_\gamma, X_{\omega_1}) \oplus \mathcal{S}(Y_\gamma, X_{\omega_1})$ .*

We now explain the structural property of  $X_{\omega_1}$  that yields the isomorphism between  $\mathcal{D}(X_\gamma)$  and  $J_{T_0}^*(A)$ .

**Definition 4.4.** Let  $X, Y$  be Banach spaces with a transfinite basis  $(x_\gamma)_{\gamma < \delta}$  and a Schauder basis  $(y_n)_n$  respectively. We say that  $Y$  is *finitely interval representable* in  $X$  (f.i.r. in short) if there exists  $C > 0$  such that for every  $n < \omega$  and  $I_1 \leq \dots \leq I_n$  not necessarily distinct intervals of  $\delta$  there exists a block sequence  $(z_l)_{l=1}^n$  with  $z_l \in \langle x_\alpha \rangle_{\alpha \in I_l}$  such that the natural mapping  $T : \langle (y_l)_{l=1}^n \rangle \rightarrow \langle (z_l)_{l=1}^n \rangle$  satisfies  $\|T\| \cdot \|T^{-1}\| < C$ .

The main reason for  $\mathcal{D}(X_\gamma) \cong J_{T_0}^*(A)$  is contained in the following fact.

**Theorem 4.5.**  *$J_{T_0}$  is f.i.r. in the closed span of any transfinite block sequence of  $X_{\omega_1}$ .*

Notice that since the basis of  $J_{T_0}$  is not unconditional, the representability of  $J_{T_0}$  derived by the previous Theorem essentially occurs only in the case of H.I.-saturated Banach spaces. We note that the relation between the representability of  $J_{T_0}$  in  $X_{\omega_1}$  and the structure of  $\mathcal{D}(X_\alpha)$  is a consequence of a minimality property described by the following result.

**Proposition 4.6.** *Suppose  $Y$  has a basis  $(y_n)_n$  which dominates the summing basis of  $c_0$ . If  $Y$  is f.i.r. in  $X_{\omega_1}$  then  $(y_n)_n$  also dominates the basis of  $J_{T_0}$ .*

We also notice that the space  $T_0$  satisfies the corresponding minimality property among all  $Y$  with an unconditional basis  $(y_n)_n$  which are finitely interval representable in  $X_{\omega_1}$ .

## 5. The unconditional counterpart

The space  $X_{u,\omega_1}$  is the counterpart of  $X_{\omega_1}$  in the frame of the spaces with an unconditional basis, similar to [6]. The space is defined as for  $X_{\omega_1}$  by a norming family of functionals  $K_{u,\omega_1}$  satisfying (1)–(4) and:

(5) It is closed under the restriction of all functionals with odd weight to every subset of  $\omega_1$ .

Although  $X_{u,\omega_1}$  belongs to the class of the spaces with an unconditional basis its study uses the same tools used in the study of  $X_{\omega_1}$ . For example, given a bounded operator  $T : X_{u,\omega_1} \rightarrow X_{u,\omega_1}$  the transfinite sequence  $(\text{dist}(Te_\gamma, \mathbb{R}e_\gamma))_{\gamma < \omega_1}$  belongs to  $c_0(\omega_1)$ , and the operator  $T$  is strictly singular if and only if the sequence  $(\|Te_\gamma\|)_{\gamma < \omega_1}$  belongs to  $c_0(\omega_1)$ .

**Theorem 5.1.** *The space  $X_{u,\omega_1}$  is nonseparable reflexive with an unconditional basis and  $\mathcal{L}(X_{u,\omega_1}) \cong \mathcal{D}(X_{u,\omega_1}) \oplus \mathcal{S}(X_{u,\omega_1})$ .*

Here  $\mathcal{D}(X_{u,\omega_1})$  denotes the space of the diagonal operators and  $\mathcal{S}(X_{u,\omega_1})$  is the space of strictly singular operators  $S$  with separable range such that  $e_\gamma^*(Se_\gamma) = 0$  for every  $\gamma < \omega_1$ .

**Corollary 5.2.** *There is a non-separable reflexive space  $X$  with an unconditional basis such that (a)  $X$  is not isomorphic to any of its proper subspaces. (b) Every bounded linear operator  $T : X \rightarrow X$  is of the form  $D + S$  with  $D$  a diagonal operator and  $S$  a strictly singular operator with separable range. (c) For every  $I_1, I_2$  infinite disjoint subsets of  $\omega_1$  the spaces  $X_{I_1}, X_{I_2}$  are totally incomparable.*

Moreover if we consider the version of  $X_{u,\omega_1}$  obtained by a universal  $\rho$ -function then the unconditional basis  $(e_\gamma)_{\gamma < \omega_1}$  is nearly subsymmetric and for any pair of disjoint infinite intervals  $I_1, I_2$  the unconditional basic sequences  $(e_\alpha)_{\alpha \in I_1}, (e_\alpha)_{\alpha \in I_2}$  are finitely equivalent while the corresponding spaces  $X_{I_1}, X_{I_2}$  are totally incomparable.
